1 Introduction

Cyber-physical systems control critical infrastructure such as water treatment facilities, power grids and transportation networks. Our proposed method significantly outperforms the baseline on every benchmark we tried, including the hardest one.

Prior work [12, 15] focused on offline detection. In contrast to prior work, our method adapts online. Results are summarized in Table 1 and Table 2.

2 Method

Our method has two steps. First, the input is encoded with a transformer; second, the anomaly score is thresholded automatically. The loss converges after a few epochs.

A limitation is that our method needs a short warm-up period.
